Problem 1

Problem Statement (Textbook 4.4.1):

Show that the norms $\|\mathbf{x}\|_\infty$, $\|\mathbf{x}\|_2$, and $\|\mathbf{x}\|_1$ satisfy the postulates (1), (2), and (3) for norms.

Norm Postulates [1, 2]:

On a vector space V, a **norm** is a function $\|\cdot\|$ from V to the set of nonnegative reals that obeys these three postulates:

$$\|x\| > 0 \text{ if } x \neq 0,\ x \in V \tag{1}$$
$$\|\lambda x\| = |\lambda|\,\|x\| \text{ if } \lambda \in \mathbb{R},\ x \in V \tag{2}$$
$$\|x + y\| \leq \|x\| + \|y\| \text{ if } x, y \in V \quad \text{(triangle inequality)} \tag{3}$$

Solution:

We verify postulates (1), (2), and (3) for $\|x\|_\infty = \max_i |x_i|$, $\|x\|_2 = \sqrt{\sum_i x_i^2}$, and $\|x\|_1 = \sum_i |x_i|$.

(a) ∞-norm: $\|x\|_\infty = \max_{1\leq i\leq n} |x_i|$

(1) If $x \neq 0$, then $\exists i$ with $x_i \neq 0$, so $|x_i| > 0$. Thus $\|x\|_\infty = \max_i |x_i| > 0$.

(2) $\|\lambda x\|_\infty = \max_i |\lambda x_i| = \max_i |\lambda||x_i| = |\lambda| \max_i |x_i| = |\lambda|\|x\|_\infty$.

(3) $\|x+y\|_\infty = \max_i |x_i + y_i| \leq \max_i(|x_i| + |y_i|) \leq \max_i |x_i| + \max_i |y_i| = \|x\|_\infty + \|y\|_\infty$.

(b) 2-norm (Euclidean): $\|x\|_2 = \sqrt{\sum_{i=1}^n x_i^2}$

(1) If $x \neq 0$, then $\exists i$ with $x_i \neq 0$, so $\sum_i x_i^2 > 0$. Thus $\|x\|_2 = \sqrt{\sum_i x_i^2} > 0$.

(2) $\|\lambda x\|_2 = \sqrt{\sum_i (\lambda x_i)^2} = \sqrt{\lambda^2 \sum_i x_i^2} = |\lambda|\sqrt{\sum_i x_i^2} = |\lambda|\|x\|_2$.

(3) Expanding $\|x+y\|_2^2$:

$$\begin{aligned}\|x+y\|_2^2 &= \sum_i (x_i+y_i)^2 = \sum_i x_i^2 + 2\sum_i x_i y_i + \sum_i y_i^2 \\ &= \|x\|_2^2 + 2\sum_i x_i y_i + \|y\|_2^2\end{aligned}$$

Since $\sum_i x_i y_i \leq \|x\|_2\|y\|_2$ (dot product bounded by product of norms):

$$\|x+y\|_2^2 \leq \|x\|_2^2 + 2\|x\|_2\|y\|_2 + \|y\|_2^2 = (\|x\|_2 + \|y\|_2)^2$$

Taking square roots: $\|x+y\|_2 \leq \|x\|_2 + \|y\|_2$.

(c) 1-norm: $\|x\|_1 = \sum_{i=1}^{n} |x_i|$

(1) If $x \neq 0$, then $\exists i$ with $x_i \neq 0$, so $|x_i| > 0$. Thus $\|x\|_1 = \sum_i |x_i| > 0$.

(2) $\|\lambda x\|_1 = \sum_i |\lambda x_i| = \sum_i |\lambda||x_i| = |\lambda| \sum_i |x_i| = |\lambda|\|x\|_1$.

(3) For each term, the triangle inequality for absolute values gives $|x_i + y_i| \leq |x_i| + |y_i|$. Summing over all i:

$$\|x + y\|_1 = \sum_i |x_i + y_i| \leq \sum_i (|x_i| + |y_i|) = \sum_i |x_i| + \sum_i |y_i| = \|x\|_1 + \|y\|_1$$

$\boxed{\text{All three norms satisfy postulates (1), (2), and (3).}}$

Problem 2

Problem Statement (Textbook 4.4.2):

Show that $\|\mathbf{x}\|_\infty \le \|\mathbf{x}\|_2 \le \|\mathbf{x}\|_1$ for all $\mathbf{x} \in \mathbb{R}^n$, and that equalities can occur, even for nonzero vectors.

Solution:

Part 1: Prove $\|x\|_\infty \le \|x\|_2$

Let $\|x\|_\infty = \max_i |x_i| = |x_k|$ for some index k. Then:

$$\|x\|_2^2 = \sum_{i=1}^{n} x_i^2 \ge x_k^2 = \|x\|_\infty^2$$

Taking square roots: $\boxed{\|x\|_\infty \le \|x\|_2}$.

Equality case: Equality holds when x has only one nonzero component. For example, $x = (5, 0, 0)^T$ gives $\|x\|_\infty = 5$ and $\|x\|_2 = 5$.

Part 2: Prove $\|x\|_2 \le \|x\|_1$

First, observe that each component satisfies $|x_i| \le \|x\|_1$ (since $\|x\|_1 = \sum_{j=1}^{n} |x_j|$ includes all terms).

For each i, we can write:

$$|x_i|^2 = |x_i| \cdot |x_i| \le |x_i| \cdot \|x\|_1$$

where the inequality holds because $|x_i| \le \|x\|_1$.

Now sum this inequality over all indices:

$$\begin{aligned}
\|x\|_2^2 = \sum_{i=1}^{n} |x_i|^2 \le \sum_{i=1}^{n} |x_i| \cdot \|x\|_1 \\
&= \|x\|_1 \sum_{i=1}^{n} |x_i| \quad \text{(factor out } \|x\|_1\text{)} \\
&= \|x\|_1 \cdot \|x\|_1 = \|x\|_1^2
\end{aligned}$$

Taking square roots of both sides: $\boxed{\|x\|_2 \le \|x\|_1}$.

Equality case: Equality holds when x has only one nonzero component. For example, $x = (0, 3, 0)^T$ gives $\|x\|_2 = 3$ and $\|x\|_1 = 3$.

Conclusion: The inequality $\boxed{\|x\|_\infty \le \|x\|_2 \le \|x\|_1}$ holds for all $x \in \mathbb{R}^n$, with equality possible for nonzero vectors.

Problem 3

Problem Statement (Textbook 4.4.3):
(Continuation) Show that $\|\mathbf{x}\|_1 \leq n\|\mathbf{x}\|_\infty$ and $\|\mathbf{x}\|_2 \leq \sqrt{n}\|\mathbf{x}\|_\infty$ for $\mathbf{x} \in \mathbb{R}^n$.

Solution:
Part 1: Prove $\|x\|_1 \leq n\|x\|_\infty$
Since $\|x\|_\infty = \max_i |x_i|$, we have $|x_i| \leq \|x\|_\infty$ for each $i = 1, 2, \ldots, n$.
Summing over all components:

$$\|x\|_1 = \sum_{i=1}^{n} |x_i| \leq \sum_{i=1}^{n} \|x\|_\infty = n\|x\|_\infty$$

Therefore: $\boxed{\|x\|_1 \leq n\|x\|_\infty}$.
Equality case: Equality holds when all components have the same absolute value. For example, $x = (1, 1, 1)^T$ gives $\|x\|_1 = 3 = 3 \cdot 1 = 3\|x\|_\infty$.

Part 2: Prove $\|x\|_2 \leq \sqrt{n}\|x\|_\infty$
Since $|x_i| \leq \|x\|_\infty$ for each i, squaring gives $|x_i|^2 \leq \|x\|_\infty^2$.
Summing over all components:

$$\|x\|_2^2 = \sum_{i=1}^{n} |x_i|^2 \leq \sum_{i=1}^{n} \|x\|_\infty^2 = n\|x\|_\infty^2$$

Taking square roots: $\boxed{\|x\|_2 \leq \sqrt{n}\|x\|_\infty}$.
Equality case: Equality holds when all components have the same absolute value. For example, $x = (2, 2, 2)^T$ gives $\|x\|_2 = \sqrt{12} = 2\sqrt{3} = \sqrt{3} \cdot 2 = \sqrt{3}\|x\|_\infty$.

Problem 4

Problem Statement (Textbook 4.4.8):

Define

$$\|A\| = \sum_{i=1}^{n}\sum_{j=1}^{n} |a_{ij}|$$

Show that this is a matrix norm (that is, a norm on the linear space of all $n \times n$ matrices). Show that it is not subordinate to any vector norm. Does it conform to Equation (9) and Inequality (10)?

$$\|I\| = 1 \quad \text{(Equation 9)}$$

$$\|AB\| \leq \|A\|\|B\| \quad \text{(Inequality 10)}$$

Solution:

Part 1: Show $\|A\|$ is a matrix norm

A matrix norm must satisfy three postulates:

(1) Positivity: If $A \neq 0$, then $\exists$ some $a_{ij} \neq 0$, so $|a_{ij}| > 0$. Thus $\|A\| = \sum_{i,j} |a_{ij}| > 0$.

(2) Homogeneity: $\|\lambda A\| = \sum_{i,j} |\lambda a_{ij}| = \sum_{i,j} |\lambda||a_{ij}| = |\lambda| \sum_{i,j} |a_{ij}| = |\lambda|\|A\|$.

(3) Triangle inequality:

$$\begin{aligned}\|A + B\| &= \sum_{i,j} |a_{ij} + b_{ij}| \leq \sum_{i,j}(|a_{ij}| + |b_{ij}|)\\ &= \sum_{i,j} |a_{ij}| + \sum_{i,j} |b_{ij}| = \|A\| + \|B\|\end{aligned}$$

$\boxed{\text{Therefore, } \|A\| \text{ is a matrix norm.}}$

Part 2: Show it is NOT subordinate to any vector norm

A subordinate (induced) matrix norm satisfies $\|I\| = 1$. However, for the identity matrix I where $(I)_{ij} = \delta_{ij}$ (Kronecker delta: $\delta_{ij} = 1$ if $i = j$, else 0):

$$\|I\| = \sum_{i=1}^{n}\sum_{j=1}^{n} |\delta_{ij}| = \sum_{i=1}^{n} 1 = n$$

Since $\|I\| = n \neq 1$ for $n > 1$, $\boxed{\text{this norm is NOT subordinate to any vector norm.}}$

Part 3: Does it conform to Equation (9)?

Equation (9) requires $\|I\| = 1$. As shown above, $\|I\| = n$.

$\boxed{\text{No, it does NOT conform to Equation (9).}}$

Part 4: Does it conform to Inequality (10)?

We need to check if $\|AB\| \leq \|A\|\|B\|$.

Step 1: We recall that for matrix multiplication, the (i, k) entry of AB is:

$$(AB)_{ik} = \sum_{j=1}^{n} a_{ij} b_{jk}$$

Step 2: Using the triangle inequality for absolute values, we have:

$$|(AB)_{ik}| = \left| \sum_{j=1}^{n} a_{ij} b_{jk} \right| \leq \sum_{j=1}^{n} |a_{ij} b_{jk}| = \sum_{j=1}^{n} |a_{ij}| |b_{jk}|$$

Step 3: We now compute $\|AB\|$ by summing over all entries:

$$\begin{aligned}
\|AB\| &= \sum_{i=1}^{n} \sum_{k=1}^{n} |(AB)_{ik}| \\
&\leq \sum_{i=1}^{n} \sum_{k=1}^{n} \sum_{j=1}^{n} |a_{ij}| |b_{jk}| \quad \text{(from Step 2)}
\end{aligned}$$

Step 4: We rearrange the triple sum. Notice that $|a_{ij}|$ doesn't depend on k, and $|b_{jk}|$ doesn't depend on i:

$$\begin{aligned}
\sum_{i=1}^{n} \sum_{k=1}^{n} \sum_{j=1}^{n} |a_{ij}| |b_{jk}| &= \sum_{i=1}^{n} \sum_{j=1}^{n} |a_{ij}| \left(\sum_{k=1}^{n} |b_{jk}| \right) \\
&= \sum_{i=1}^{n} \sum_{j=1}^{n} |a_{ij}| \cdot \sum_{k=1}^{n} \sum_{j=1}^{n} |b_{jk}| \\
&= \left(\sum_{i=1}^{n} \sum_{j=1}^{n} |a_{ij}| \right) \left(\sum_{j=1}^{n} \sum_{k=1}^{n} |b_{jk}| \right) \\
&= \|A\| \cdot \|B\|
\end{aligned}$$

Step 5: Combining Steps 3 and 4, we obtain: $\|AB\| \leq \|A\| \|B\|$.

$\boxed{\text{Yes, it DOES conform to Inequality (10).}}$

Problem 5

Problem Statement (Textbook 4.4.11):

Show that for the vector norm $\|\mathbf{x}\|_1$ defined in Equation (5), the subordinate matrix norm is

$$\|A\|_1 = \max_{1 \leq j \leq n} \sum_{i=1}^{n} |a_{ij}|$$

where

$$\|\mathbf{x}\|_1 = \sum_{i=1}^{n} |x_i| \quad \text{(Equation 5)}$$

Solution:

We need to show that the subordinate matrix norm induced by $\|\mathbf{x}\|_1$ is the maximum absolute column sum.

Recall that the subordinate matrix norm is defined as:

$$\|A\|_1 = \max_{\mathbf{x} \neq \mathbf{0}} \frac{\|A\mathbf{x}\|_1}{\|\mathbf{x}\|_1}$$

Equivalently, we can write:

$$\|A\|_1 = \max_{\|\mathbf{x}\|_1 = 1} \|A\mathbf{x}\|_1$$

Part 1: Upper Bound ($\|A\|_1 \leq \max_j \sum_i |a_{ij}|$)

For any vector $\mathbf{x}$ with $\|\mathbf{x}\|_1 = 1$, we compute:

$$\begin{aligned}
\|A\mathbf{x}\|_1 &= \sum_{i=1}^{n} \left| \sum_{j=1}^{n} a_{ij} x_j \right| \\
&\leq \sum_{i=1}^{n} \sum_{j=1}^{n} |a_{ij}||x_j| \quad \text{(triangle inequality)} \\
&= \sum_{j=1}^{n} |x_j| \sum_{i=1}^{n} |a_{ij}| \quad \text{(interchange sums)} \\
&\leq \sum_{j=1}^{n} |x_j| \cdot \max_{1\leq k\leq n} \sum_{i=1}^{n} |a_{ik}| \\
&= \left(\sum_{j=1}^{n} |x_j| \right) \cdot \max_{1\leq k\leq n} \sum_{i=1}^{n} |a_{ik}| \\
&= \|\mathbf{x}\|_1 \cdot \max_{1\leq k\leq n} \sum_{i=1}^{n} |a_{ik}| \\
&= \max_j \sum_{i=1}^{n} |a_{ij}|
\end{aligned}$$

This holds for all $\mathbf{x}$ with $\|\mathbf{x}\|_1 = 1$, so:

$$\|A\|_1 \leq \max_j \sum_{i=1}^{n} |a_{ij}|$$

Part 2: Lower Bound (Equality is Achieved)

Let j^* be the column index that achieves the maximum:

$$j^* = \arg \max_{1\leq j\leq n} \sum_{i=1}^{n} |a_{ij}|$$

Now choose the test vector $\mathbf{x}^* = \mathbf{e}_{j^*}$ (the j^*-th standard basis vector), which has $\|\mathbf{x}^*\|_1 = 1$.

Then:

$$A\mathbf{x}^* = A\mathbf{e}_{j^*} = \begin{bmatrix} a_{1,j^*} \\ a_{2,j^*} \\ \vdots \\ a_{n,j^*} \end{bmatrix}$$

Thus:

$$\|A\mathbf{x}^*\|_1 = \sum_{i=1}^{n} |a_{i,j^*}| = \max_j \sum_{i=1}^{n} |a_{ij}|$$

This shows that the upper bound is achieved, so:

$$\|A\|_1 \geq \max_j \sum_{i=1}^{n} |a_{ij}|$$

Conclusion

Combining Parts 1 and 2:

$$\boxed{\|A\|_1 = \max_{1 \leq j \leq n} \sum_{i=1}^{n} |a_{ij}|}$$

The subordinate matrix norm induced by the 1-norm is the **maximum absolute column sum**.

Problem 6

Problem Statement (Textbook 4.4.33):

For any $n \times n$ matrix A, define

$$\|A\|_F = \left(\sum_{i=1}^{n} \sum_{j=1}^{n} a_{ij}^2 \right)^{1/2}$$

(This is called the **Frobenius** norm.) Is this a subordinate matrix norm? Answer the same question for $\|A\| = \max_{1 \le i,j \le n} |a_{ij}|$. Prove that these equations define norms on the vector space of all $n \times n$ matrices.

Solution:

Problem 7

Problem Statement (Textbook 4.6.1b):
Program the Gauss-Seidel method and test it on the following system:

$$\begin{aligned} 3x + y + z &= 5 \\ 3x + y - 5z &= -1 \\ x + 3y - z &= 3 \end{aligned}$$

Analyze what happens when these systems are solved by simple Gaussian elimination without pivoting.

Solution:
System Matrix:

$$A = \begin{bmatrix} 3 & 1 & 1 \\ 3 & 1 & -5 \\ 1 & 3 & -1 \end{bmatrix}, \quad b = \begin{bmatrix} 5 \\ -1 \\ 3 \end{bmatrix}$$

True Solution (using direct method): $\boxed{x = y = z = 1}$

Part 1: Gauss-Seidel Method

The Gauss-Seidel iteration is:

$$\begin{aligned} x^{(k+1)} &= \frac{1}{3}(5 - y^{(k)} - z^{(k)}) \\ y^{(k+1)} &= \frac{1}{1}(-1 - 3x^{(k+1)} + 5z^{(k)}) \\ z^{(k+1)} &= \frac{1}{-1}(3 - x^{(k+1)} - 3y^{(k+1)}) \end{aligned}$$

Diagonal Dominance Check:

- Row 1: $|a_{11}| = 3 > |1| + |1| = 2$
- Row 2: $|a_{22}| = 1 \not> |3| + |-5| = 8$
- Row 3: $|a_{33}| = |-1| = 1 \not> |1| + |3| = 4$

$\boxed{\text{Matrix is NOT strictly diagonally dominant}}$
Convergence Results (see `hw05_p07.jl`):

- Starting from $(1, 1, 1)$: **Converges in 1 iteration** (already at solution!)
- Starting from $(0.999, 0.999, 0.999)$: **Diverges** (NaN)
- Starting from $(1.01, 1.01, 1.01)$: **Diverges** (NaN)

- Starting from $(0.9, 0.9, 0.9)$ or $(1.1, 1.1, 1.1)$: **Diverges** (NaN)
- Starting from $(0, 0, 0)$, $(5, -1, 3)$, or $(10, 10, 10)$: **Diverges** (NaN)

Key Observation: The method only "converges" when starting exactly at the solution. Even tiny perturbations (0.001 away) cause catastrophic divergence to NaN. This demonstrates **complete instability**.

Part 2: Gaussian Elimination without Pivoting

Forward elimination proceeds:

Step 1: Eliminate column 1 using pivot $a_{11} = 3$:

$$\begin{bmatrix} 3 & 1 & 1 \\ 0 & 0 & -6 \\ 0 & 8/3 & -4/3 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} 5 \\ -6 \\ 4/3 \end{bmatrix}$$

Step 2: Attempt to eliminate column 2 using pivot a_{22}:

$$\boxed{a_{22} = 0 \text{ (ZERO PIVOT!)}}$$

Analysis:

- Gaussian elimination **fails** due to zero pivot at position $(2, 2)$
- Rows 2 and 3 need to be swapped (partial pivoting required)
- Without pivoting, the method cannot proceed
- The system has determinant $\det(A) = 48 \neq 0$, so the matrix is invertible
- Failure is due to *method limitation*, not matrix singularity

Summary: Both methods encounter difficulties with this system:

- **Gauss-Seidel:** Diverges for most starting points (not diagonally dominant)
- **Gaussian Elimination:** Fails without pivoting (zero pivot encountered)

Implementation: See Appendix A for complete Julia code listings:

- Gauss-Seidel method: Appendix
- Gaussian elimination: Appendix

Problem 8

Problem Statement (Textbook 6.1.1d):

Find the polynomial of least degree that interpolates these sets of data:

x	3	7	12
y	12	146	2

Solution:

We find the polynomial of least degree interpolating the data points $(3, 12)$, $(7, 146)$, and $(12, 2)$.

Since we have 3 data points, the interpolating polynomial has degree at most $n - 1 = 2$ (quadratic).

Method: Vandermonde Matrix

We seek a polynomial $P(x) = a_0 + a_1 x + a_2 x^2$ such that $P(x_i) = y_i$ for $i = 1, 2, 3$.

This gives the linear system (see Textbook p. 313, Equation 12) [1]:

$$\begin{bmatrix} 1 & x_1 & x_1^2 \\ 1 & x_2 & x_2^2 \\ 1 & x_3 & x_3^2 \end{bmatrix} \begin{bmatrix} a_0 \\ a_1 \\ a_2 \end{bmatrix} = \begin{bmatrix} y_1 \\ y_2 \\ y_3 \end{bmatrix}$$

Substituting our data:

$$\begin{bmatrix} 1 & 3 & 9 \\ 1 & 7 & 49 \\ 1 & 12 & 144 \end{bmatrix} \begin{bmatrix} a_0 \\ a_1 \\ a_2 \end{bmatrix} = \begin{bmatrix} 12 \\ 146 \\ 2 \end{bmatrix}$$

Solving this system, we obtain:

$$a_0 = -\frac{4211}{18} \approx -233.8667$$
$$a_1 = \frac{1849}{18} \approx 102.7222$$
$$a_2 = -\frac{125}{18} \approx -6.9222$$

Implementation: See Appendix B (**??**) for Julia code implementation.

Final Answer:

$$\boxed{P(x) = -\frac{125}{18}x^2 + \frac{1849}{18}x - \frac{4211}{18}}$$

Or in decimal form:

$$\boxed{P(x) = -6.9222x^2 + 102.7222x - 233.8667}$$

Verification:

- $P(3) = 12.000$

- $P(7) = 146.000$
- $P(12) = 2.000$

Maximum interpolation error: 5.68×10^{-14} (numerical precision).

Problem 9

Problem Statement (Textbook 6.1.8):

Discuss the problem of determining a polynomial of degree at most 2 for which $p(0)$, $p(1)$, and $p(\xi)$ are prescribed, ξ being any preassigned point.

Solution:

We seek a polynomial $p(x) = a_0 + a_1 x + a_2 x^2$ (degree at most 2) such that:

$$p(0) = y_0, \quad p(1) = y_1, \quad p(\xi) = y_\xi$$

where y_0, y_1, y_ξ are prescribed values and ξ is a given point.

Main Case: Three Distinct Points Required

For a polynomial of degree at most 2, we need three distinct interpolation points. Thus, we require:

$$\boxed{\xi \neq 0 \text{ and } \xi \neq 1}$$

The Vandermonde system is:

$$\begin{bmatrix} 1 & 0 & 0 \\ 1 & 1 & 1 \\ 1 & \xi & \xi^2 \end{bmatrix} \begin{bmatrix} a_0 \\ a_1 \\ a_2 \end{bmatrix} = \begin{bmatrix} y_0 \\ y_1 \\ y_\xi \end{bmatrix}$$

The determinant is:

$$\det(V) = \xi(\xi - 1)$$

Since $\xi \neq 0$ and $\xi \neq 1$, we have $\det(V) \neq 0$, so the system has a **unique solution**.

Conclusion: When $\xi \notin \{0, 1\}$, there exists a **unique polynomial of degree at most 2** satisfying all three conditions.

Degenerate Cases

Note: If $\xi = 0$ or $\xi = 1$, we only have two distinct interpolation points, which contradicts the requirement for a degree-2 polynomial. In these cases:

- The problem reduces to linear interpolation (degree at most 1)
- The prescribed values must be consistent (e.g., if $\xi = 0$, then $y_0 = y_\xi$)
- The resulting polynomial is the line through the two distinct points

These cases defeat the original question's intent of determining a degree-2 polynomial.

Key Insight: The problem is well-posed if and only if we have three distinct interpolation points, i.e., $\xi \notin \{0, 1\}$.

A.1 Gauss-Seidel Method Implementation

```julia
function gauss_seidel(A, b, x0; max_iter=100, tol=1e-10)
    n = length(b)
    x = copy(x0)
    history = [copy(x)]

    for iter in 1:max_iter
        x_old = copy(x)

        # Gauss-Seidel iteration
        for i in 1:n
            sum_val = b[i]
            for j in 1:n
                if j ≠ i
                    sum_val -= A[i, j] * x[j]
                end
            end
            x[i] = sum_val / A[i, i]
        end

        push!(history, copy(x))

        # Check convergence
        error = norm(x - x_old, Inf)
        if error < tol
            return (x, true, iter, history)
        end
    end

    return (x, false, max_iter, history)
end
```

Figure 1: Julia code implementing the Gauss-Seidel iterative method for Problem 7.

A.2 Gaussian Elimination without Pivoting

```julia
function gaussian_elimination_no_pivot(A, b)
    n = length(b)
    A_work = copy(A)
    b_work = copy(b)

    # Forward elimination
    for k in 1:n-1
        println(@sprintf("\nStep %d: Eliminate column %d", k, k))

        if abs(A_work[k, k]) < 1e-14
            println("  ⚠ WARNING: Pivot element is near zero!")
            println(@sprintf("    a_%d%d = %.2e", k, k, A_work[k, k]))
            return (zeros(n), false, A_work, b_work)
        end

        println(@sprintf("  Pivot: a_%d%d = %.6f", k, k, A_work[k, k]))

        for i in k+1:n
            if abs(A_work[i, k]) > 1e-14
                multiplier = A_work[i, k] / A_work[k, k]
                println(@sprintf("  Row %d: subtract %.6f × Row %d", i, multiplier, k))

                A_work[i, k:n] -= multiplier * A_work[k, k:n]
                b_work[i] -= multiplier * b_work[k]
            end
        end

        println("\n  Matrix after step $k:")
        display(A_work)
        println("\n  RHS after step $k:")
        display(b_work)
    end
```

Figure 2: Julia code implementing Gaussian elimination without pivoting (Part 1).

```julia
    # Back substitution
    x = zeros(n)
    for i in n:-1:1
        x[i] = (b_work[i] - dot(A_work[i, i+1:n], x[i+1:n])) / A_work[i, i]
    end

    return (x, true, A_work, b_work)
end
```

Figure 3: Julia code implementing Gaussian elimination without pivoting (Part 2).
