A conjugate gradient algorithm for "linear systems" 1. Given: Xo 2. Set: 10 = Axo-b, Po = -ro, Ke 0 3. Compute next iterate ar = TriPr PrAPr XKH < XK+ XKPK Updates why? Each new conjugate direction 13 PKH - AXKHI-b chosen to be BEHI C PEAPE Pen = - Ten + Bren Pr for some Bun regume PKH APK = 0 => BKH as shown! PKH - CKH + BKH PK K- K+1 If rx = 0 then stop Notice that each successive conjugate otherwise goto step 3 direction depends only on the previous direction A, b, and ourrent residual r. Contrast this with a Gram-Schmidt method which regumes knowledge of all previous directions. Key Ideas on Convergence Theorem 5.4: If A has r distinct eigenvalues, then CG terminates in no more than r iterations. Theorem 5.5: If A has eigenvalues $\lambda_1 \neq \lambda_2 \leq \cdots \leq \lambda_n$, then co satisfies 11 Xxxxx - X = 1 = (\frac{\lambda_{n-k} - \lambda_1}{\lambda_{n-k} + \lambda_1})^2 11 \text{X}_0 - \text{X} = 1 \\ \frac{\lambda_{n-k} - \lambda_1}{\lambda_{n-k} - \lambda_1} \\ \frac{\lambda_{n-k} - \lambda_1}{\lambda_{n-k} - \lambda_1} \\ \frac{\lambda_{n-k} - \lambda_1}{\lambda_{n-k} - \lambda_1} \\ \frac{\lambda_n}{\lambda_n} = \lambda_1 \\ \frac{\lambda_n}{\lamb example $\lambda = 1, 1, 1, 2, 3, 5, 8$ $|| x_1 - x^* ||^2 \leq |7/q| || x_0 - x^* ||^2$ $|| x_2 - x^* ||^2 \leq |4/6| || x_0 - x^* ||^2$ $|| x_3 - x^* ||^2 \leq |2/4| || x_0 - x^* ||^2$ $|| Y_5 - x^* ||^2 \leq (0) || X_0 - x^* ||^2$

Using the following properties of conjugate directions:

$$r_{k}^{T} p_{j} = 0$$
 $r_{k}^{T} r_{j} = 0$
 $j = 1, 2, ..., k-1$
 $p_{k}^{+} A p_{j} = 0$

We can rewrite the algorithm into a more symmetric and useful form:

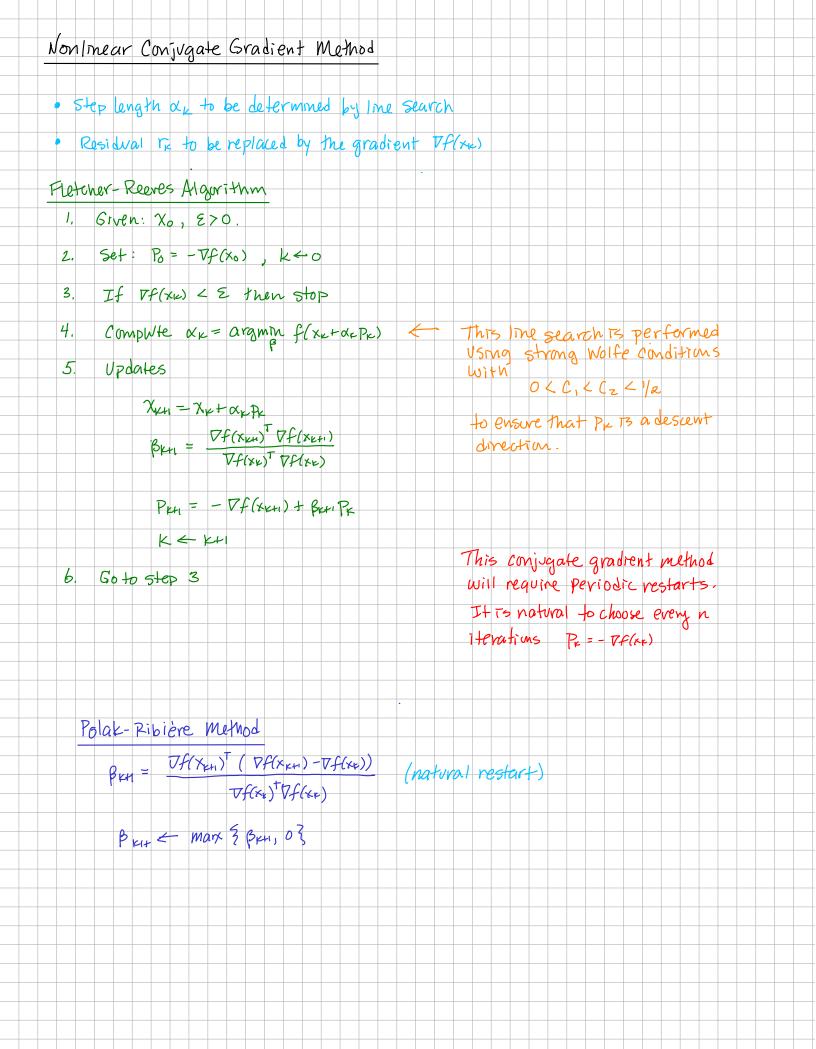

- 1. Given: Xo
- 2. Set: 10 = Axo-b, Po - ro, KGO
- 3. Compute next iterate

$$\alpha_{k} \leftarrow \frac{r_{k}^{T}r_{k}}{P_{k}^{T}AP_{k}} = \frac{||r_{k}||^{2}}{||P_{k}||_{A}^{2}}$$

XKH < XK+ XKPK

4. Updales

5. If
$$r_k = 0$$
 then stop otherwise goto step 3
